Abstract

A simple, yet accurate, meshless method for the solution of thin plates undergoing large deflections is presented. The solution is based on the use of fifth order polynomial radial basis function to build an approximation for the solution of two coupled nonlinear differential equations governing the finite deflection of thin plates. The resulted nonlinear algebraic equations are solved using an incremental-iterative procedure. The accuracy and efficiency of the method is verified through several numerical examples.

Keywords: RBF; Meshless; Plate; Finite deflection

1. Introduction

In some applications of thin elastic plates, the deflections may increase under loading conditions beyond a certain limit recognized as large deformations. Because of these large deformations, the midplane stretches and hence produces considerable in-plane stresses that are neglected by the small-deflection bending theory. For instance, in the case of a clamped circular plate subjected to a uniform load that produces a central deflection of 100% of its thickness, the maximum stretching stress is approximately 40% of the maximum bending stress [1]. For such situations, an extended plate theory must be employed, accounting for the effect of large deflection. Large elastic deflection of a thin elastic plate is governed by coupled nonlinear differential equations for which analytical solutions are available only for very few cases involving simple geometries and loading conditions [1–5]. For other cases, the problem has to be solved using numerical techniques such as the finite-difference method (FDM), the finite-element method (FEM) and the boundary-element method (BEM).

Nevertheless, the possibility of obtaining numerical solutions without resorting to the mesh-based techniques mentioned above, has been the goal of many researchers throughout the computational mechanics community for the past two decades or so. Radial basis function (RBF) is one of the most recently developed meshless methods that has attracted attention in recent years, especially in the area of computational mechanics [6–8]. This method does not require mesh generation which makes them advantageous for 3-D problems as well as problems that require frequent re-meshing such as those arising in nonlinear analysis. Due to its simplicity to implement, it represents an attractive alternative to FDM, FEM and BEM as a solution method of nonlinear differential equations. However, it is only since rather recently that RBF has been used to approximate solutions for partial differential equations and therefore this area is still relatively unexplored.

The roots of RBF goes back to the early 1970s, when it was used for fitting scattered data [9]. In 1982, Nardini and Brebbia [10] coupled RBF with BEM in a technique called dual-reciprocity BEM to solve free-vibration problems, where the RBF was used to transform the domain integrals into boundary integrals. Thereafter, many researchers have used RBF in conjunction with BEM to solve various problems in computational mechanics. The method, however, has not been applied directly to solve partial
differential equations until 1990 by Kansa [11,12]. Since then, many researchers have suggested several variations to the original method, e.g., Refs. [13–18] not to mention many others. In general, RBF method expands the solution of a problem in terms of RBFs and chooses expansion coefficients such that the governing equations and boundary conditions are satisfied at some selected domain and boundary points. However, one of the important issues in applying this technique is the determination of the proper form of RBF for a given differential equation. Most of the available RBFs involve a parameter, called shape factor, which needs to be selected so that the required accuracy of the solution is attained. In this paper, the simple fifth order polynomial RBF that does not involve a shape factor is considered. The objective of this paper is to offer a simple mesh-free method for the solution of thin elastic plates undergoing large deflection. The method is also applicable to other nonlinear problems in various areas of computational mechanics. The paper is organized as follows. The governing equations based on w–F formulation are presented in Section 2. In Section 3, the RBF method as applied to the large deflection of thin plates is illustrated. The incremental-iterative procedure for solving the resulting RBF coupled nonlinear equations is explained in Section 4. The efficiency of the method is demonstrated by numerical examples in Section 5, followed by some concluding remarks in Section 6.

2. Governing equations

The details of the derivation of equations governing the finite deflection of thin plates are given in the classical book by Timoshenko [1]. The equations are represented here for clarity and in order to refer to them during various stages of the numerical solution. Let us denote the membrane forces acting in the middle plane of the plate by \( N_x, N_y \) and \( N_{xy} \). In the absence of body forces, the equations of equilibrium along \( x \) and \( y \) are given by

\[
\frac{\partial N_x}{\partial x} + \frac{\partial N_{xy}}{\partial y} = 0, \\
\frac{\partial N_{xy}}{\partial x} + \frac{\partial N_y}{\partial y} = 0.
\]

The third equation necessary to determine the three quantities \( N_x, N_y \) and \( N_{xy} \) is obtained from a consideration of the strain in the middle surface of the plate during bending. The corresponding strain components are

\[
e_x = \frac{\partial u}{\partial x} + \frac{1}{2} \left( \frac{\partial w}{\partial x} \right)^2, \\
e_y = \frac{\partial v}{\partial y} + \frac{1}{2} \left( \frac{\partial w}{\partial y} \right)^2.
\]

By taking the second derivative of these expressions and combining the resulting equations, it can be shown that

\[
\frac{\partial^2 e_x}{\partial y^2} + \frac{\partial^2 e_y}{\partial x^2} = \frac{\partial^2 e_{xy}}{\partial x \partial y} = \left( \frac{\partial^2 w}{\partial x \partial y} \right)^2 - \frac{\partial^2 w}{\partial x^2} \frac{\partial^2 w}{\partial y^2}.
\]

By replacing the strain components by the following equivalent expressions:

\[
e_x = \frac{1}{hE} (N_x - \nu N_y), \\
e_y = \frac{1}{hE} (N_y - \nu N_x), \\
\gamma_{xy} = \frac{1}{hG} N_{xy},
\]

the third equation in terms of \( N_x, N_y \) and \( N_{xy} \) is obtained. The solution of these equations is greatly simplified by the introduction of a stress function \( F \). It may be seen that Eqs. (1) and (2) are identically satisfied by taking

\[
N_x = h \frac{\partial^2 F}{\partial y^2}, \quad N_y = h \frac{\partial^2 F}{\partial x^2}, \quad N_{xy} = -h \frac{\partial^2 F}{\partial x \partial y},
\]

where \( F \) is a function of \( x \) and \( y \). If these expressions for the forces are substituted in Eqs. (7)–(9), the strain components become

\[
e_x = \frac{1}{E} \left( \frac{\partial^2 F}{\partial y^2} - \nu \frac{\partial^2 F}{\partial x^2} \right), \\
e_y = \frac{1}{E} \left( \frac{\partial^2 F}{\partial x^2} - \nu \frac{\partial^2 F}{\partial y^2} \right), \\
\gamma_{xy} = -2(1 + \nu) \frac{\partial^2 F}{E \partial x \partial y}.
\]

Substituting these expressions in Eq. (6), we obtain

\[
\nabla^4 F = E \left[ \left( \frac{\partial^2 w}{\partial x \partial y} \right)^2 - \left( \frac{\partial^2 w}{\partial x^2} \right) \left( \frac{\partial^2 w}{\partial y^2} \right) \right],
\]

which is the first equation relating \( w \) and \( F \). The second equation necessary to determine \( F \) and \( w \) is derived from the bending action [1] which is given by

\[
\nabla^4 w = \frac{h}{D} \left[ q + \frac{\partial^2 F}{\partial y^2} \left( \frac{\partial^2 w}{\partial x^2} \right) + \frac{\partial^2 F}{\partial x^2} \left( \frac{\partial^2 w}{\partial y^2} \right) - 2 \left( \frac{\partial^2 F}{\partial x \partial y} \right) \left( \frac{\partial^2 w}{\partial x \partial y} \right) \right].
\]

The transverse boundary conditions considered here are given by

\[
BC_{w1}(w) = 0 \text{ where } BC_{w1}(w) = w \text{ or } BC_{w1}(w) = V_n, \\
BC_{w2}(w) = 0 \text{ where } BC_{w2}(w) = \frac{\partial w}{\partial y} \text{ or } BC_{w2}(w) = M_n,
\]
where \( M_n \) and \( V_n \) are the normal bending moment and effective shear force that are given by

\[
M_n = - D \left\{ v \nabla^2 w + (1 - v) \left( n_x^2 \frac{\partial^2 w}{\partial x^2} + n_y^2 \frac{\partial^2 w}{\partial y^2} \right) + 2n_x n_y \frac{\partial^2 w}{\partial x \partial y} \right\},
\]

\[
V_n = - D \left\{ \left( n_y (1 - n_x^2 (v - 1)) \right) \frac{\partial^3 w}{\partial y^3} + n_x \left( -2n_x^2 (v - 1) + n_y^2 (v - 1) + v \right) \frac{\partial^3 w}{\partial y^2 \partial x} + n_x \left( n_y^2 (v - 1) - 2n_x^2 (v - 1) + v \right) \frac{\partial^3 w}{\partial x^2 \partial y} + n_x \left( 1 - n_x^2 (v - 1) \right) \frac{\partial^3 w}{\partial x^3} \right\},
\]

where \( n_x \) and \( n_y \) are the \( x \) and \( y \) components of the unit vector normal to the boundary. The boundary conditions for the stress function \( F \) are obtained by assuming that the external edge of the plate is not subjected to inplane forces \([1]\), which yields the following boundary conditions:

\[
F = \frac{\partial F}{\partial n} = 0.
\]

The solution of Eqs. (14) and (15), together with the boundary conditions (16)–(20), determines the two functions \( F \) and \( w \). On having the stress function \( F \), we can determine the stresses in the middle surface of a plate by applying Eqs. (10).

### 3. RBF formulation

Consider the 2-D computational domain (Fig. 1) that represents the plate geometry. For collocation, we use node points distributed both along the boundary \( (x^B_j, j = 1, ..., N_B) \), and over the interior \( (x^D_j, j = 1, ..., N_D) \). Let \( x \equiv (x^B, x^D) \), so that the total number of points called poles is \( N_p = N_B + N_D \). The deflection, \( w \), is interpolated linearly by suitable RBFs:

\[
w(x) = \sum_{j=1}^{N_B} \phi^j (\|x - x^B_j\|) + \sum_{j=1}^{N_B} \phi^j (\|x - x^D_j\|) + \sum_{j=1}^{N_B} \phi^j B_{w} \left( \|x - x^B_j\| \right) + \sum_{j=1}^{N_B} \phi^j B_{w} \left( \|x - x^D_j\| \right),
\]

\[
F(x) = \sum_{j=1}^{N_B} \phi^j (\|x - x^B_j\|) + \sum_{j=1}^{N_B} \phi^j (\|x - x^D_j\|) + \sum_{j=1}^{N_B} \phi^j B_{F} \left( \|x - x^B_j\| \right) + \sum_{j=1}^{N_B} \phi^j B_{F} \left( \|x - x^D_j\| \right),
\]

where \( \phi = ||x - x^B||^n = r^n \) is a polynomial RBF of \( n \)th degree. Unlike the other RBFs, the polynomial RBF has the important advantage of being free of a shape factor which is a source of solution instability if not properly selected. It should be noted that there are some constraints on the permissible values of the polynomial degree \( n \). This is explained by Table 1 that shows the results of the bi-harmonic operator \( \nabla^4 \phi \) for different degrees of the polynomial RBF, \( n \).

The bi-harmonic operator versus degree of RBF polynomial
following matrix form:

\[
\begin{bmatrix}
BC_{w1}(\Phi) & BC_{w1}(BC_{w1}(\Phi)) & BC_{w1}(BC_{w2}(\Phi)) \\
BC_{w2}(\Phi) & BC_{w2}(BC_{w1}(\Phi)) & BC_{w2}(BC_{w2}(\Phi)) \\
\nabla^4 \Phi & \nabla^4(BC_{w1}(\Phi)) & \nabla^4(BC_{w2}(\Phi))
\end{bmatrix}
\begin{bmatrix}
x_w^1 \\
x_w^2 \\
x_w^3
\end{bmatrix}
= \begin{bmatrix}
0 \\
0 \\
\frac{\partial NL(w, F)}{\partial \beta w}
\end{bmatrix}
\]

The above linear equations are then solved for the coefficients \(x_w, \beta_w, \) and \(\gamma_w\).

(2) Use the first estimates of \(x_w, \beta_w, \) and \(\gamma_w\) in Eq. (21) to obtain the first estimate of deflection \(w_1\). Note that \(w_1\) corresponds to the solution of small-deflection theory for the first increment.

(3) Calculate \(NL(w_1^1, w_1^1)\) and solve (24) for the first estimates of coefficients \(x_F, \beta_F, \) and \(\gamma_F\).

(4) Use first estimates for the coefficients \(x_F, \beta_F, \) and \(\gamma_F\) in Eq. (22) to obtain the first estimate of the stress function \(F_1^1\).

(5) Update the right hand side of (23) by calculating \(NL(w_1^1, F_1^1)\) and solve for the updated values of the coefficients \(f_w, \beta_w, \) and \(\gamma_w\).

(6) Use Eq. (21) to obtain the second estimate of deflection \(w_2\) and calculate \(NL(w_2^1, w_2^1)\).

(7) Repeat the above steps until convergence is achieved, otherwise, decrease the load increment and repeat the iterations.

(8) Add the second load increment \((q = 2q/n)\) and use the values obtained for \(NL(w_2^1, F_2^1)\) at the last iteration of the first load increment, then repeat the above iterative procedure.

(9) Continue adding increments until the total load is applied.

4. Incremental-iterative procedure

In order to solve the above coupled and highly nonlinear equations, an incremental-iterative procedure is performed. In the following, the superscripts represent increments while subscripts represent iterations. As an example, the quantity \(w_{x,y}^k\) represents the second derivative of \(w\) with respect to \(x\) for the \(k\)th increment and \(j\)th iteration. Let us denote the number of increments by \(n\). The following steps describe the incremental-iterative procedure:

(1) Apply the first load increment \(q/n\) and set the initial values of the second derivatives of \(w\) and \(F\) to zero, i.e. \(F_{0,x}^1 = F_{0,y}^1 = F_{0,xx}^1 = w_{0,x}^1 = w_{0,xx}^1 = w_{0,xy} = w_{0,yy} = 0\), so that \(NL(w_0^0, F_0^0) = 0\) and Eq. (23) becomes

\[
\begin{bmatrix}
BC_{w1}(\Phi) & BC_{w1}(BC_{w1}(\Phi)) & BC_{w1}(BC_{w2}(\Phi)) \\
BC_{w2}(\Phi) & BC_{w2}(BC_{w1}(\Phi)) & BC_{w2}(BC_{w2}(\Phi)) \\
\nabla^4 \Phi & \nabla^4(BC_{w1}(\Phi)) & \nabla^4(BC_{w2}(\Phi))
\end{bmatrix}
\begin{bmatrix}
x_w \\
x_w \\
x_w
\end{bmatrix}
= \begin{bmatrix}
0 \\
0 \\
\frac{\partial NL(w, F)}{\partial \beta w}
\end{bmatrix}
\]

(2) Use the first estimates of \(x_w, \beta_w, \) and \(\gamma_w\) in Eq. (21) to obtain the first estimate of deflection \(w_1\). Note that \(w_1\) corresponds to the solution of small-deflection theory for the first increment.

(3) Calculate \(NL(w_1^1, w_1^1)\) and solve (24) for the first estimates of coefficients \(x_F, \beta_F, \) and \(\gamma_F\).

(4) Use first estimates for the coefficients \(x_F, \beta_F, \) and \(\gamma_F\) in Eq. (22) to obtain the first estimate of the stress function \(F_1^1\).

(5) Update the right hand side of (23) by calculating \(NL(w_1^1, F_1^1)\) and solve for the updated values of the coefficients \(f_w, \beta_w, \) and \(\gamma_w\).

(6) Use Eq. (21) to obtain the second estimate of deflection \(w_2\) and calculate \(NL(w_2^1, w_2^1)\).

(7) Repeat the above steps until convergence is achieved, otherwise, decrease the load increment and repeat the iterations.

(8) Add the second load increment \((q = 2q/n)\) and use the values obtained for \(NL(w_2^1, F_2^1)\) at the last iteration of the first load increment, then repeat the above iterative procedure.

(9) Continue adding increments until the total load is applied.
A flow chart representing the above algorithm is given in Fig. 2.

5. Numerical examples

In order to examine the effectiveness of the proposed RBF method for large deflection of thin plates, the following three examples are considered. The accuracy of RBF solutions are compared with the analytical and FEM solutions. All FEM solutions are obtained using the package ANSYS 9.0 [19]. In all examples, the load is assumed to be uniformly distributed $q$. Poisson ratio $\nu$ is assumed 0.3. For generality of the solutions, all quantities are made dimensionless, so that the coordinates, the load, the deflection and the stress are represented by $\bar{x} = x/a$, $\bar{y} = y/a$, $\bar{q} = qa^4/Eh^4$, $\bar{w} = w/h$ and $\bar{\sigma} = \sigma a^2/Eh^2$, respectively. In all examples, the load is increased until the central deflection exceeds 100% of the plate thickness.

Example 1. Consider a simply supported circular plate subjected to a uniformly distributed load $q$ which is increased from 0.125 to 2 with equal increments of 0.125. The following approximate analytical solutions for the problem is given by Timoshenko [1]:

\[ \bar{w}_c + A\bar{w}_c^3 = B\bar{q}, \]  
\[ \bar{\sigma}_m = z\bar{w}_c^2, \]  
\[ \bar{\sigma}_b = \beta\bar{w}_c^2, \]

where $\bar{w}_c$ is central deflection, $\bar{\sigma}_m$ the stress in the plate middle plane (membrane stress), and $\bar{\sigma}_b$ the extreme fiber bending stress. The constants are $A = 0.262$, $B = 0.696$, $z = 0.295$ and $\beta = 1.778$. The RBF and FEM solutions are obtained by employing a uniform nodal distribution consisting of 32 boundary nodes and 69 domain nodes as shown in Fig. 3. The evolution of the plate deflection at its plate center with the applied load is presented in Fig. 4 which reveals total agreement among RBF, FEM and the analytical solutions. The results for membrane and bending stresses at the center of the plate are given in Fig. 5 which shows excellent agreement between RBF and FEM solutions. The same figure shows deviations of both RBF and FEM solutions from the analytical solution especially for bending stress at higher loads. The deviations of the numerical solutions from the analytical solution can be attributed to the acknowledged inherent approximation of the analytical solution [1].

Example 2. Let us repeat example 1 by assuming a clamped edge boundary condition. The analytical solution is given by Eqs. (25)–(27), where $A = 0.146$, $B = 0.171$, $z = 0.5$ and $\beta = 2.86$. The deflection and stress solutions of the problem are given in Figs. 6 and 7, respectively. The results for this example share the same observation of example 1 concerning the deviation of the numerical solutions from the analytical solution for the bending stress at high loads.

Example 3. Consider a simply supported square plate subjected to a uniformly distributed load $q$ which is increased from 2 to 32 with equal increments of 2. There is no analytical solution available for this problem and therefore the RBF solution is compared with FEM solution only. The problem is modeled using a uniform nodal distribution consisting of 36 boundary nodes and 81
domain nodes as shown in Fig. 8. The results for maximum deflection and stresses are presented in Figs. 9 and 10, respectively. Both figures show excellent agreement between RBF and FEM solutions.

6. Conclusions

A simple meshless method for the analysis of thin plates undergoing large deflections is presented. The method is based on collocations with the fifth order polynomial radial basis function (RBF). This RBF does not require a shape parameter that needs to be specified as the case for other well-known RBFs. In addition, the method shares the same advantage of other RBF methods that do not require the computation of integrals or use of grids and meshes. The method can be easily extended to other nonlinear problems.
