USING THE METHOD OF FUNDAMENTAL SOLUTIONS IN CONJUNCTION WITH THE DEGENERATE KERNEL IN CYLINDRICAL ACOUSTIC PROBLEMS

I-Lin Chen

ABSTRACT

This paper proposes applications of the method of fundamental solutions (MFS) to exterior acoustic radiation and scattering problems. By using the two-point function of fundamental solutions, the coefficients of influence matrices are easily determined. It is found that this method also produces irregular frequencies as well as the boundary element method does. The position of the irregular frequency depends on the source point location. To avoid this numerical instability, the mixed-layer potential method is employed to deal with the problem. Based on the circulant properties and degenerate kernels, an analytical scheme in the discrete system of a cylinder is achieved to demonstrate the existence of irregular frequencies. Three numerical examples of uniform radiation, nonuniform radiation and scattering problems of a circular cylinder are examined and are compared with the results by using direct BEM.

Key Words: method of fundamental solutions, two-point function, irregular frequency, circulant, degenerate kernels.

I. INTRODUCTION

In numerical methods, mesh generation for complicated geometry is always time consuming in the stage of model creation for engineers dealing with engineering problems by employing the finite difference method (FDM), finite element method (FEM) or boundary element method (BEM). Over the past decade, researchers have paid attention to the meshless method without employing the concept of elements. The initial idea of the meshless method dates back to the smooth particle hydrodynamics (SPH) method for modeling astrophysical phenomena (Gingold and Maragah, 1977). Several meshless methods have also been reported in the literature, for example, the domain-based methods including the element-free Galerkin method (Belytschko et al., 1994), the reproducing kernel method (Liu et al., 1995), and boundary-based methods including the boundary node method (Mukherjee and Mukherjee, 1997), the meshless local Petrov-Galerkin approach (Atluri and Zhu, 1998), the local boundary integral equation method (Sladek et al., 2000), the RBF approach (Chen et al., 1998; Golberg et al., 2000; Zhang et al., 2000) and the method of fundamental solutions (MFS) (Kondapalli et al., 1992; Poullikkas et al., 2002). The MFS is a technique for the numerical solution of certain elliptic boundary value problems, and it may be viewed as an indirect boundary element method with a concentrated source instead of a distributed one (Chen et al., 2000). Like the boundary element method, it is applicable when a fundamental solution of the differential equation in question is known. The basic idea is to approximate the solution by forming a linear combination of fundamental solutions with sources located outside the problem domain. The coefficients of the linear combination are determined so that the approximate solution satisfies the problem boundary conditions. Poullikkas et al. (2002) employed MFS to solve three-dimensional electrostatics, and only a few sources were adopted. Cisilino and Sensale (2002) developed a simulated annealing algorithm for the Laplace equation, to decide the
optimal position of source points by using the MFS. However, the drawback of the method is that it is complicated to compute and so the benefit of the MFS is lost. Ramachandran (2002) adopted the singular value decomposition (SVD) technique, by truncating the nearly zero singular value, to resolve the ill-posed problem in the MFS. Kondapalli et al. (1992) applied the MFS to acoustic scattering in fluids and solids. Further details are found in the review paper by Fairweather and Karageorghis (1998) on the MFS approach.

One of the problems frequently addressed in BEM is the problem of irregular (fictitious) frequencies for exterior acoustics. Kondapalli (1992) pointed out that the difficulty of fictitious frequencies appearing in the BEM is not present in the MFS. The reason is that a discrete set of source points does not define an internal surface uniquely, as quoted from Fairweather et al., 2003. In this paper, we will examine this point for the fictitious frequency phenomenon in the MFS.

The fictitious frequencies do not represent any kind of physical resonance but are due to the numerical method, which does not have a unique solution at some eigenfrequencies for corresponding interior problems (Dokumaci, 1990; Lee et al., 1996; Lee and Sclavounos, 1989; Malenica and Chen, 1998; Ohmatsu, 1983; Ursell, 1981). It was found that BEM results in fictitious eigenvalues, which are associated with the interior frequency of the Dirichlet problem. The general derivation has been provided by a continuous system (Chen, 1998), and a discrete system using a circulant (Kuo et al., 2000; Chen and Kuo, 2000). Following the retracted BEM formulation (Hwang and Chang, 1991), it was found that the position of the irregular frequency depends on the source location. Wilton et al., 1993, proved the equivalence between the superposition method and the layer potential method. Since the non-uniqueness problem exists in the layer potential method, fictitious frequencies also appear in the superposition method. In the numerical examples, they demonstrated the appearance of fictitious frequencies in three-dimensional cases in the superposition method. The MFS and the retracted BEM can be seen as similar indirect methods instead of the difference between a lump source and a distributed source.

The fictitious frequency in exterior acoustic problems is similar to the spurious eigenvalues which occur in the annular eigenproblem when the MFS is used. The positions of spurious eigenvalues for the annular problem depend on the location of the inner fictitious boundary when the sources are distributed (Chen et al., 2005). The spurious eigenvalues appearing in the single and double-layer MFS were found to be the interior eigenvalues corresponding to the Dirichlet and Neumann problems, respectively. A similar mechanism in exterior acoustics will be examined in this paper.

In order to obtain a unique solution that is known to exist analytically, several approaches for BEM that provide additional constraints to the original system of equations have been proposed. Burton and Miller (1971) proposed an integral equation that was valid for all wave numbers by forming a linear combination of the singular integral equation and its normal derivative. Numerical examples for nonuniform radiation problems using the dual BEM were provided and irregular frequencies were easily found (Chen et al., 2003). Although the fictitious frequencies can be predicted theoretically (Chen, 1998; Chen and Kuo, 2000), we may not find the positions of numerical instability from the real computations for some cases, and how to explain the reason for this is not trivial.

This paper will study the mechanism of fictitious-frequencies in exterior acoustics by using the MFS. An analytical study of the fictitious frequency in a discrete system for a circular cylinder is conducted by using the degenerate kernel and circulants. Three numerical examples of uniform radiation, nonuniform radiation and scattering problems of a circular cylinder are also examined and are compared with the analytical solution and the results from using the direct BEM.

II. THE MFS FORMULATION FOR HELMHOLTZ EQUATION

The boundary value problem to be solved can be stated as follows: The acoustic pressure \( u(x) \) must satisfy the Helmholtz equation,

\[
\nabla^2 u(x) + k^2 u(x) = 0, \quad x \in D
\]

where \( k = \omega c \) is the wave number and \( \omega \) is the angular frequency and \( D \) is the domain of interest. By using the MFS, the acoustic field and flux can be described by linear combinations of fundamental solutions:

\[
\begin{align*}
  u(x) &= \sum_{j=1}^{N} U(s_j, x) \Gamma(s_j) \\
  t(x) &= \sum_{j=1}^{N} L(s_j, x) \Gamma(s_j)
\end{align*}
\]

2. Double-Layer Potential Approach (TM Method)

\[
\begin{align*}
  u(x) &= \sum_{j=1}^{N} T(s_j, x) \Omega(s_j) \\
  t(x) &= \sum_{j=1}^{N} M(s_j, x) \Omega(s_j)
\end{align*}
\]
where \(x\) and \(s\) are the collocation and source points, respectively, as shown in Fig. 1, \(L(s, x) \equiv \frac{\partial U(s, x)}{\partial n_s}\);
\[ T(s, x) \equiv \frac{\partial U(s, x)}{\partial n_s}; \quad M(s, x) \equiv \frac{\partial^2 U(s, x)}{\partial n_s \partial n_s}; \quad t(x) \equiv \frac{\partial u(s)}{\partial n_s} \]
is the normal vector; \(\Gamma(s)\) and \(\Omega(s)\) are the general-
ized unknowns for the densities of single and double-
layer potential, respectively, at \(s\); \(2N\) is the number of collocation points; and \(U(s, x)\) is the fundamental solution, which satisfies
\[ \nabla^2 U(s, x) + k^2 U(s, x) = 2\pi\delta(s - x) \] (6)
in which \(\delta\) is the Dirac delta function. The four kernels are,
\[ U(s, x) = -\frac{i\pi}{2} H_0^{(1)}(kr) \] (7)
\[ T(s, x) = \frac{\partial U(s, x)}{\partial n_s} = \frac{i\pi k_0}{2} \frac{H_1^{(1)}(kr)y_i\pi_i}{r} \] (8)
\[ L(s, x) = \frac{\partial^2 U(s, x)}{\partial n_s \partial n_s} = -\frac{i\pi k_0}{2} \frac{H_1^{(1)}(kr)y_i\pi_i}{r^2} + \frac{H_1^{(1)}(kr)y_i\pi_i}{r} \] (9)
\[ M(s, x) = \frac{\partial^2 U(s, x)}{\partial n_s \partial n_s} \]
where \(r \equiv |s - x|\) is the distance between the source and collocation points; \(\vec{n}_s\) is the ith component of the outnormal vector at \(s\); \(n_i\) is the ith component of the outnormal vector at \(s\); \(H_1^{(1)}\) denotes the first kind of the \(n\)th order Hankel functions; and \(y_i \equiv s_i - x_i\), \(i = 1, 2\), are the differences of the \(i\)th components of \(s\) and \(x\).

We consider an infinite circular cylinder with the Dirichlet boundary condition
\[ u(x) = \vec{u}, \quad x \in B \] (11)
where \(B\) is the boundary.

By matching the boundary conditions for \(x\) on the \(2N\) boundary points into Eqs. (2) and (3) we have
\[ \{u\} = [U]\{\Gamma\} \] (12)
\[ \{t\} = [L]\{\Gamma\} \] (13)
where \([\Gamma]\) is the vectors of undetermined coefficients. If \(k\) is not the fictitious frequency, Eq. (12) can be rearranged to
\[ \{\Gamma\} = [U]^{-1}\{\vec{u}\} \] (14)
\[ \{t\} = [L]\{\Gamma\} \]

We obtain the unknown boundary density \(\{t\}\) as follows:
\[ \{t\} = [L][U]^{-1}\{\vec{u}\} = [SD]\{\vec{u}\} \] (15)
where \([SD] = [L][U]^{-1}\) denotes the matrix by using the Single-layer potential approach for the Dirichlet problem. By substituting Eq. (14) into Eq.(2), we obtain the field pressure
\[ u(x) = <w(x)\rangle [U]^{-1}\{\vec{u}\} \] (16)
where \(<w>\) is the influence row vector of the field point obtained by using the \(U(s, x)\) kernel.

Now, we consider another case with the Neumann boundary conditions
\[ t(x) = \vec{t}, \quad x \in B \] (17)
By matching the boundary conditions for \(x\) on the \(2N\) boundary points into Eq. (3), we have
\[ \{\vec{t}\} = [L]\{\Gamma\} \] (18)
and Eq. (18) can be rearranged to
\[ \{\Gamma\} = [L]^{-1}\{\vec{t}\} \] (19)
We obtain the unknown boundary density \(\{u\}\) as follows:
\[ \{u\} = [U][L]^{-1}\{\vec{t}\} = [SN]\{\vec{t}\} \] (20)
where \([SN] = [U][L]^{-1}\) denotes the matrix by using the Single-layer potential approach for the Neumann problem. By substituting Eq. (19) into Eq. (2), we obtain the field pressure for the Neumann boundary condition
\[ u(x) = <w(x)\rangle [L]^{-1}\{\vec{t}\} \] (21)
Similarly, by matching the boundary conditions for \( x \) on the 2N boundary points into Eq. (4), we have

\[
\{ \ddot{u} \} = [T]\{ \Omega \}
\]  
(22)

where \( \{ \Omega \} \) represents the vectors of undetermined coefficients. Eq. (22) can be rearranged to

\[
\{ \Omega \} = [T]^{-1}\{ \ddot{u} \}
\]  
(23)

We can obtain the unknown boundary density \( \{ t \} \) as follows:

\[
\{ t \} = [M][T]^{-1}\{ \ddot{u} \} = [DD]\{ \ddot{u} \}
\]  
(24)

where \( [DD] = [M][T]^{-1} \) denotes the matrix, by using the Double-layer potential approach for the Dirichlet problem. By substituting Eq. (23) into Eq. (4), we obtain the field pressure

\[
u(x) = <v> [T]^{-1}\{ \ddot{u} \},
\]  
(25)

where \(<v>\) is the influence row vector of the field point obtained by using the \( T(s, x) \) kernel. Similarly, considering the Neumann boundary condition, \( t(x) = T \), we have

\[
\{ T \} = [M]\{ \Omega \}
\]  
(26)

Eq. (26) can be rearranged to

\[
\{ \Omega \} = [M]^{-1}\{ T \}
\]  
(27)

We can obtain the unknown boundary density \( \{ u \} \) as follows:

\[
\{ u \} = [T][M]^{-1}\{ T \} = [DN]\{ T \}
\]  
(28)

where \( [DN] = [T][M]^{-1} \) denotes the matrix by using the Double-layer potential approach for the Neumann problem. By substituting Eq. (27) into Eq. (4), we obtain the field pressure for the Neumann boundary condition

\[
u(x) = <v> [M]^{-1}\{ \ddot{u} \}
\]  
(29)

III. ANALYTICAL STUDY OF THE IRREGULAR FREQUENCY FOR THE CIRCULAR RADIATOR USING CIRCULANTS IN THE DISCRETE SYSTEM

For the circular case, we can express \( x = (\rho, \phi) \) and \( s = (R, \theta) \) in terms of polar coordinates. The four kernels can be expressed in terms of degenerate kernels as shown below:

\[
U(s, x) = \left\{ \begin{array}{ll}
U^i(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n(k \rho) + Y_n(k \rho) J_n(k \rho) \cos(n \theta - \phi)\}, & R > \rho \\
U^e(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n(k \rho) + Y_n(k \rho) J_n(k \rho) \cos(n \theta - \phi)\}, & R < \rho
\end{array} \right.
\]
(30)

\[
T(s, x) = \left\{ \begin{array}{ll}
T^i(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n'(k \rho) + Y_n'(k \rho) J_n'(k \rho) \cos(n \theta - \phi)\}, & R > \rho \\
T^e(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n'(k \rho) + Y_n'(k \rho) J_n'(k \rho) \cos(n \theta - \phi)\}, & R < \rho
\end{array} \right.
\]
(31)

\[
L(s, x) = \left\{ \begin{array}{ll}
L^i(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n'(k \rho) + Y_n'(k \rho) J_n'(k \rho) \cos(n \theta - \phi)\}, & R > \rho \\
L^e(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n'(k \rho) + Y_n'(k \rho) J_n'(k \rho) \cos(n \theta - \phi)\}, & R < \rho
\end{array} \right.
\]
(32)

\[
M(s, x) = \left\{ \begin{array}{ll}
M^i(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n'(k \rho) + Y_n'(k \rho) J_n'(k \rho) \cos(n \theta - \phi)\}, & R > \rho \\
M^e(R, \theta; \rho, \phi) = \sum_{n=-\infty}^{\infty} \frac{k \pi}{2} \{-i J_n'(k \rho) + Y_n'(k \rho) J_n'(k \rho) \cos(n \theta - \phi)\}, & R < \rho
\end{array} \right.
\]
(33)

where \( J_n \) and \( Y_n \) are the first and second Bessel functions with order \( n \), and the superscripts “\(^i\)” and “\(^e\)” denote the interior \( (R > \rho) \) and exterior domains \( (R < \rho) \), respectively.

Since the rotation symmetry is preserved for a circular boundary, the four influence matrices in Eqs. (2)-(5) are denoted by \([U]\), \([L]\), \([T]\) and \([M]\) of the circulants with the elements...
where the kernel $K$ can be $U$, $T$, $L$ or $M$, $\phi$ and $\theta$ are the angles of observation and source points, respectively. By superimposing $2N$ lumped strength along the boundary, we have the influence matrices,

$$K = K(R, \theta; \rho, \phi)$$  \hspace{1cm} (34)

where $a_{j-i} = K(s_j, x_i)$

(35)

$$K = \begin{bmatrix}
a_0 & a_1 & a_2 & \cdots & a_{2N-2} & a_{2N-1} \\
a_{2N-1} & a_0 & a_1 & \cdots & a_{2N-3} & a_{2N-2} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
a_1 & a_2 & a_3 & \cdots & a_{2N-1} & a_0
\end{bmatrix}
$$

The matrix $[K]$ in Eq. (35) is found to be a circulant since the rotational symmetry for the influence coefficients is considered. By introducing the following bases for the circulants, $L$, $(C_{2N})^1$, $(C_{2N})^2$, $\ldots$, and $(C_{2N})^{2N-1}$, we can expand $[K]$ into

$$[K] = a_0I + a_1(C_{2N})^1 + a_2(C_{2N})^2 + \ldots + a_{2N-1}(C_{2N})^{2N-1}$$  \hspace{1cm} (36)

where $I$ is a unit matrix and

$$C_{2N} = \begin{bmatrix}
0 & 1 & 0 & \cdots & 0 & 0 \\
0 & 0 & 1 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & 0 & 1 \\
1 & 0 & 0 & \cdots & 0 & 0
\end{bmatrix}_{2N \times 2N}$$  \hspace{1cm} (37)

Based on the circulant theory, the eigenvalues for the influence matrices $[K]$ and $[C_{2N}]$, are found as follows:

$$\lambda_\ell = a_0 + a_1\alpha_\ell + a_2\alpha_\ell^2 + \cdots + a_{2N-1}\alpha_\ell^{2N-1},$$  \hspace{1cm} (38)

$$\ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$

where $\lambda_\ell$ and $\alpha_\ell$ are the eigenvalues for $[K]$ and $[C_{2N}]$, respectively. It is easily found that the eigenvalues for the circulant $[C_{2N}]$ are the roots of $\alpha^{2N} = 1$ as shown below:

$$\alpha_\ell = e^{\frac{2\pi i \ell}{2N}}, \ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$  \hspace{1cm} (39)

Substituting Eq. (39) into Eq. (38), we have

$$\lambda_\ell = \sum_{m=0}^{2N-1} a_m\alpha_\ell^m = \sum_{m=0}^{2N-1} a_m e^{\frac{2\pi i \ell m}{2N}},$$  \hspace{1cm} (40)

$$\ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$

According to the definition for $a_m$ in Eq. (36), we have

$$a_m = a_{2N-m}, m = 0, 1, 2, \ldots, 2N-1$$  \hspace{1cm} (41)

Substituting Eq. (42) into Eq. (41) yields

$$\lambda_\ell = a_0 + (-1)^\ell a_N + \sum_{m=1}^{N-1} (\alpha_\ell^m + \alpha_\ell^{2N-m})a_m$$

$$= \sum_{m=0}^{N-1} \cos(m\ell \Delta \theta)a_m$$  \hspace{1cm} (42)

Putting Eq. (36) into Eq. (43) for the case $U$ of $K$ for $\phi = 0$ without loss of generality, the Riemann sum of infinite terms reduces to the following integral

$$\lambda_\ell = \lim_{N \to \infty} \sum_{m=0}^{2N-1} \cos(m\ell \Delta \theta)(U(m\Delta \theta, 0)$$

$$= \frac{1}{\rho \Delta \theta} \int_0^{2\pi} \cos(\ell \theta)U(\theta, 0)\rho d\theta$$  \hspace{1cm} (43)

where $\Delta \theta = \frac{2\pi}{2N}$. By using the degenerate kernel for $U(s, x)$ in Eq. (30) and the orthogonal conditions, Eq. (40) reduces to

$$\lambda_\ell = -i\pi^2 \rho H_i^{(1)}(k\rho)J_\ell(kR),$$  \hspace{1cm} (44)

$$\ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$

Similarly, we have

$$\mu_\ell = -ik\pi^2 \rho H_i^{(1)}(k\rho)J_\ell(kR),$$  \hspace{1cm} (45)

$$\ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$

$$\nu_\ell = -ik\pi^2 \rho H_i^{(1)}(k\rho)J_\ell(kR),$$  \hspace{1cm} (46)

$$\ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$

$$\kappa_\ell = -ik\pi^2 \rho H_i^{(1)}(k\rho)J_\ell(kR),$$  \hspace{1cm} (47)

$$\ell = 0, \pm 1, \pm 2, \ldots, \pm (N-1), N$$

where $\mu$, $\nu$ and $\kappa$ are the eigenvalues of $[L]$, $[T]$ and $[M]$ matrices, respectively. The determinants for the four matrices are obtained by multiplying the eigenvalues as shown below:

$$\det[U] = \lambda_0(\lambda_1\lambda_2 \cdots \lambda_{N-1})^2 \lambda_N$$  \hspace{1cm} (48)

$$\det[L] = \mu_0(\mu_1\mu_2 \cdots \mu_{N-1})^2 \mu_N$$  \hspace{1cm} (49)

$$\det[T] = \nu_0(\nu_1\nu_2 \cdots \nu_{N-1})^2 \nu_N$$  \hspace{1cm} (50)
\[ \text{det}[M] = \kappa_0 (\kappa_1 \kappa_2 \cdots \kappa_{N-1})^2 \kappa_N \]  

(52)

Since the four matrices \([U] \), \([L] \), \([T] \) and \([M] \) are all symmetric circulants, they can be expressed by

\[
[U] = \Phi \sigma_0 \sigma_1 \cdots \sigma_{N-1} \Phi^{-1}
\]

(53)

\[
[L] = \Phi \sigma_0 \sigma_1 \cdots \sigma_{N-1} \Phi^{-1}
\]

(54)

\[
[T] = \Phi \sigma_0 \sigma_1 \cdots \sigma_{N-1} \Phi^{-1}
\]

(55)

\[
[M] = \Phi \sigma_0 \sigma_1 \cdots \sigma_{N-1} \Phi^{-1}
\]

(56)

where \( \Phi \) is the unitary matrix.

1. Derivation of Fictitious Frequency by Using the Single-Layer Potential Approach

For the Dirichlet problem, by employing Eqs. (53) and (54) for Eq. (15), we have

\[
\text{det}[SD] = \text{det} \Phi \sigma_0 \sigma_1 \cdots \sigma_{N-1} \Phi^{-1}
\]

(57)

\[
\text{det} \Phi^{-1} = \sigma_0 \sigma_1 \cdots \sigma_{N-1} \sigma_N \Phi^{-1}
\]

(58)

where the superscript “SD” denotes using the single-layer potential approach for the Dirichlet problem and

\[
\sigma_0^{(SD)} = \frac{H_0^{(1)}(ka)J_1(kR)}{H_1^{(1)}(ka)J_1(kR)}, \quad \ell = 0, \pm 1, \pm 2, \cdots, \pm (N-1), N
\]

(60)

Since \( H_1^{(1)}(ka) \) is never zero for any value of \( k \), the \( k \) value satisfying Eq. (60), implies

\[
J_1(kR) = 0
\]

(61)

For the Neumann problem, by employing Eqs. (53) and (54) for Eq. (20), we have
where the superscript “SN” denotes the Neumann problem using the single-layer potential approach and

\[
\sigma^{(SN)}_\ell = \frac{H^{(1)}_\ell(ka)J'_\ell(kR)}{H^{(1)}_\ell(ka)J_k(kR)}, \quad \ell = 0, \pm 1, \pm 2, \cdots, \pm (N-1), N
\]

According to Eqs. (62) and (63), we have

\[
\det[\Phi] = \det[\Phi]_{\sigma_0^{(SN)}}(\sigma_2^{(SN)}\cdots \sigma_{N-1}^{(SN)})^2 \sigma_N^{(SN)} \det[\Phi^{-1}]
\]

\[
= \sigma_0^{(SN)}(\sigma_2^{(SN)}\cdots \sigma_{N-1}^{(SN)})^2 \sigma_N^{(SN)}
\]

(64)

Based on Eq. (67), the numerical instability of zero divided by zero occurs at the denominator where \( k \) satisfies

\[
H^{(1)}_\ell(ka)J'_\ell(kR) = 0, \quad \ell = 0, \pm 1, \pm 2, \cdots, \pm (N-1), N
\]

(65)

Since the term \( H^{(1)}_\ell(ka) \) is never zero for any value of \( k \), the \( k \) value satisfying Eq. (65), implies

\[
J'_\ell(kR) = 0
\]

(66)

**2. Derivation of Fictitious Frequency by Using the Double-Layer Potential Approach**

Similarly, for the Dirichlet problem, by employing Eqs. (55) and (56) for Eq. (24), we have

\[
\sigma^{(DD)}_\ell = \frac{H^{(1)}_\ell(ka)J_\ell(kR)}{H^{(1)}_\ell(ka)J_k(kR)}, \quad \ell = 0, \pm 1, \pm 2, \cdots, \pm (N-1), N
\]

(67)

where the superscript “DD” denotes the Dirichlet problem using the double-layer potential approach.
Kondapalli et al., 1992. The reason cited was that the fictitious frequencies in the MFS are different from those of derived BEM by a ratio of 2, since the radius of the sphere connected by the source points is half of the real boundary. The first fictitious frequency for the three-dimensional case occurs at the position of $k = \frac{2\pi}{r}$, instead of $k = \frac{\pi}{r}$ in the BEM. That is the reason why they could not find the fictitious frequencies in the range of $0 < k < 5$.

IV. MIXED-LAYER POTENTIAL METHOD

In the exterior acoustics of the Helmholtz equation using dual BEM, the mixed-layer potential method (Hwang and Chang, 1991) utilized the product of double-layer equations with an imaginary constant to the single-layer equation to deal with the fictitious frequency which is the non-unique solution problem. We will extend this concept to MFS.

$$u(x_i) = \sum_j (U(s_j, x_i) + \frac{i}{k} T(s_j, x_i)) \varphi(s_j)$$  \hspace{1cm} (74)

$$t(x_i) = \sum_j (L(s_j, x_i) + \frac{i}{k} M(s_j, x_i)) \varphi(s_j)$$  \hspace{1cm} (75)

where $\varphi$ is the mixed potential.

V. NUMERICAL EXAMPLES

Case 1: Uniform radiation from an infinite circular cylinder (Dirichlet boundary condition)

For the first example, a radiation problem is considered. The boundary condition is shown in Fig. 2. The normalized analytical solution to this cylinder problem with a radius $a = 1.0$ m is

$$u(\rho, \phi) = \frac{H_4^{(1)}(k\rho)}{H_4^{(1)}(ka)} \cos(4\phi), \quad \rho \geq a, \quad 0 \leq \phi < 2\pi$$  \hspace{1cm} (76)

subjected to boundary condition $u(a, \phi) = \cos(4\phi)$, $0 \leq \phi < 2\pi$.

where $H_4^{(1)}(k\rho)$ denotes the first-kind Hankel function of the fourth order. Sixty source points and sixty collocation points are adopted. The source points are located at $R = 0.9$ m. Fig. 3 shows the contour plot for the real-part solutions with $ka = 1.0$. The positions where the irregular values occur can be found, are showing in Fig. 4 for the solution $t$ versus $k$ at the position $a = 1$, $\phi = 0$ by using the MFS method and direct BEM. It is found that no irregular values can be found between zero and eight. At the position of $k = 8.43$, the numerical instability appears, since the value is the first zero of $J_4(kR)$ for the MFS method. The irregular value occurs at $k = 7.58$ when using the direct BEM. The fictitious frequency of the MFS differs from the value of direct BEM by a ratio of $7.58 \approx 0.9$, as predicted analytically. The performance of the MFS in comparison with the analytical solution, and the mixed-layer potential approach is quite good, as shown in Fig. 5.

Case 2: Nonuniform radiation from an infinite circular cylinder (Neumann boundary condition)
This problem was chosen because the exact solution is known (Harari et al., 1998). The boundary condition is shown in Fig. 6. In this example we computed the nonuniform radiation from an infinite circular cylinder, and the Neumann boundary condition is applied to the cylinder surface. The portion \((-\alpha < \theta < \alpha)\) is assigned a unit value, while the remaining portion is assigned a homogeneous value. The analytical solution to this cylinder problem with a radius \(a = 1.0\) m is given by

\[
 u(\rho, \phi) = 2\sum_{n=0}^{\infty} \frac{-1}{k} \frac{\sin(n\alpha)}{n} \frac{H_n^{(1)}(k\rho)}{H_n^{(1)}(ka)} \cos(n\phi),
\]

\(\rho > a, 0 < \phi < 2\pi\) \hspace{1cm} (77)

where the symbol ‘denotes that the first term \((n = 0)\) is halved. We select \(\alpha = \frac{5\pi}{16}\), and \(ka = 1\). Fig. 7 shows the contour plots for the real part of the numerical solutions. Sixty-four nodes are adopted in the MFS and \(\alpha = \frac{5\pi}{16}\) for this case. The source points are located at \(R = 0.9\) m. The positions where the irregular values occur can be found in Fig. 8 for the solution \(u(a, 0; k)\) versus \(k\). It is found that by using the UL formulation the irregular values occur at the positions of \(J_{n,m}\), which is the mth zero of \(J_n(kR)\). The fictitious frequencies which occurred at the position are described in Eq. (61). By using the TM formulation the irregular values occur at the positions of \(J_{n,m}'\), which is the \(m\)th zero of \(J_n'(kR)\). The results of the MFS, the mixed-layer potential approach and analytical solution are shown in Fig. 8. Figs. 9(a)-(c) show the surface potential for \(k = 1.0\) by using the UL, TM and mixed-layer potential, respectively. The results of Fig. 9c, are worse than those of Figs. 9a and 9b. Although the three results are different, they all can be acceptable from a numerical viewpoint. Figs. 10(a)-(c) show the surface potential for \(k = 2.67\) by using the UL, TM and mixed-layer potential, respectively, which corresponds to the first interior Dirichlet eigenproblem. In Fig. 10 (a) the result using the UL formulation shows some
error compared to the analytical solution, as described in Eq. (66). Figs. 11(a)-(c) show the surface potential for \( k = 2.09 \) by using the UL, TM and mixed-layer potential method, respectively, which corresponds to the first interior Neumann eigenproblem. In Fig. 11(b) the result using the TM formulation shows a large error compared to the analytical solution, as described in Eq. (72).

**Case 3: Plane wave scattering for a rigid infinite circular cylinder (Neumann boundary condition)**

In order to check the validity of the program for the scattering problem, example 3 is considered (Harari et al., 1997). The incident wave is a plane wave and the scatter is a rigid cylinder, as shown in Fig. 12. Sixty nodes are adopted for this case. The analytical solution for the scattering field is

\[
u(\rho, \theta) = \frac{J_0'(ka)}{H_0^{(1)}(ka)}H_0^{(1)}(k\rho) - 2 \sum_{n=1}^{\infty} i^n \frac{J_n'(ka)}{H_n^{(1)}(ka)}H_n^{(1)}(k\rho) \cos(n\theta)
\]

(Fig. 78)

Figs. 13 and 14 show the contour plot for the real-part solution of MFS and analytical at \( ka = 4\pi \), respectively. The results of the MFS in comparison with the analytical solution are quite good. The positions where the
irregular values occur can be found in Fig. 15 for the solution \( u(a, 0; k) \) versus \( k \). Sixty-four nodes are adopted in the MFS. The source points are located at \( R = 0.9 \) m. It is found that by using the UL formulation the irregular values also occur at the zeros of \( J_{n,m} \). By using the TM formulation the irregular values also occur at the zeros of \( J'_{n,m} \). The results for the MFS, analytical solution and the mixed-layer potential solution agree well, as shown in Fig. 15.

VI. CONCLUSIONS

This paper examines why fictitious frequencies occur in the MFS by considering the radiation and scattering problems of a cylinder. Based on the circulant properties and degenerate kernels, an analytical scheme for a discrete system of a cylinder was achieved. The occurrence of a fictitious frequency depends only on the formulation, not on the specified boundary condition. The numerical results from this study indicate that the irregular frequency also appears at the eigenvalue of the interior problem.
where the boundary is connected by the source locations instead of the real boundary used in the direct BEM. In a circular cylinder case, the position of irregular frequency depends on the source location $R$. The mixed-layer potential method was demonstrated successfully to filter out the fictitious frequency analytically and numerically.

**NOMENCLATURE**

$B$  
the boundary of the domain

$c$  
sound speed

$D$  
domain of interest

$H_n^{(1)}$  
the first kind Hankel function with order $n$

$i$  
$i^2 = -1$, imaginary unit

$J_n$  
the first kind Bessel function with order $n$

$k$  
wave number

$L(s, x)$  
kernel function of the second dual integral equation

$M(s, x)$  
kernel function of the second dual integral equation

$n_i$  
the $i$th component of the outnormal vector at the source point $s$

$n_i$  
the $i$th component of the outnormal vector at field point $x$

$n_s$  
the outnormal direction at the field point $x$

$n_s$  
the outnormal direction at the source point $s$

$r$  
distance between the source and field points, $r = |x - s|$

$SVD$  
singular value decomposition

$T(s, x)$  
kernel function of the first dual integral equation

$t(x)$  
normal flux on the field point $x$

$U(s, x)$  
kernel function of the first dual integral equation

$u(x)$  
potential on the field point $x$

$Y_n$  
the second kind Bessel function with order $n$

$y_i$  
$x_i - s_i$

$\kappa$, $\lambda$, $\mu$, $\nu$, $\alpha$  
eigenvalues

$\sigma_i$  
singular value

$\varphi$  
the mixed potential

$\nabla^2$  
Laplacian operator

$\Gamma$  
the vectors of undetermined coefficients

$\Omega$  
the vectors of undetermined coefficients

$\Phi$  
unitary matrix of SVD

$\omega$  
angular frequency
