An infinite plane problem with a circular boundary under the screw dislocation is solved by using a new method. The angle-based fundamental solution for screw dislocation is expanded into degenerate kernel. Our method can explain why the image screw dislocation is required. Besides, the location of the image point can be obtained easily by using degenerate kernel after satisfying boundary conditions. Even though the image concept is required, the location of image point can be determined straightforwardly through the degenerate kernels instead of the method of reciprocal radii. Finally, two examples are demonstrated to verify the validity of the present method.

## 1. Introduction

The dislocation theory is essential for understanding many physical and mechanical properties of crystalline solids. Many researchers investigated the dislocation problems in the past years. Smith [1] successfully solved the problem of the interaction between a screw dislocation and a circular or elliptic inclusion contained within an infinite body subject to a uniform applied shear stress at infinity by using the complex-variable function and circle theorem. Dundurs [2] solved the screw dislocation with circular inclusion problem by using the image technique. Later, Sendecyk [3] employed the complex-variable function in conjunction with the inverse point method to solve the problem of the screw dislocation near an arbitrary number of circular inclusions. Almost all above problems were solved by using the complex-variable technique. Its extension to three-dimensional cases may be limited. A more general approach is nontrivial for further investigation.

**Figure 2:** Sketch of the concentrated source and the screw dislocation.

Similarly, the field point  $x$  can be expressed by  $z_x = \rho e^{i\phi}$  in the complex plane as shown in Figure 2. By decomposing the  $\ln(z_x - z_s)$  into real and imaginary parts, we have

$$\ln(z_x - z_s) = \ln(re^{i\psi}) = \ln r + i\psi. \quad (2.1)$$

The real part ( $\ln r$ ) is the fundamental solution of the source singularity while the imaginary part ( $\psi$ ) denotes the fundamental solution of the screw dislocation. For the exterior case ( $R < \rho$ ), (2.1) can be expanded as follows:

$$\begin{aligned} \ln(z_x - z_s) &= \ln(z_x) + \ln\left(1 - \frac{z_s}{z_x}\right) \\ &= \ln(\rho e^{i\phi}) - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{z_s}{z_x}\right)^m \\ &= \ln \rho + i\phi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R e^{i\theta}}{\rho e^{i\phi}}\right)^m \\ &= \ln \rho + i\phi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R}{\rho}\right)^m [\cos m(\theta - \phi) + i \sin m(\theta - \phi)]. \end{aligned} \quad (2.2)$$

Thus, the degenerate form for the fundamental solution of the screw dislocation,  $\psi(s, x)$ , can be expressed as

$$\psi(s, x) = \phi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R}{\rho}\right)^m \sin m(\theta - \phi), \quad \rho > R. \quad (2.3)$$

Similarly, we have

$$\psi(s, x) = \theta + \pi + \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{\rho}{R}\right)^m \sin m(\theta - \phi), \quad \rho < R, \quad (2.4)$$

for the interior case. In Figure 2, the range of  $\psi(s, x)$  is defined between 0 and  $2\pi$ . To match the physical meaning and mathematical requirement, we modify the range of interest between  $-\pi$  and  $\pi$ . Thus, the fundamental solution of the screw dislocation  $\psi(s, x)$  is expressed by

$$\psi(s, x) = \begin{cases} \psi^I(\rho, \phi; R, \theta) = \theta + \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{\rho}{R}\right)^m \sin m(\theta - \phi), & \rho < R, \\ \psi^E(\rho, \phi; R, \theta) = \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R}{\rho}\right)^m \sin m(\theta - \phi), & \rho > R, \end{cases} \quad (2.5)$$

where the superscripts  $I$  and  $E$  denote the interior and exterior cases, respectively. It is noted that the denominator in (2.5) involves the larger argument to ensure the series convergence. The displacement contour of the screw dislocation in the four quadrants by using (2.5) is shown in Figures 3(a)–3(d). When the screw dislocation locates at the four quadrants, there are certain areas falling outside the range between  $-\pi$  and  $\pi$ . We subtract  $2\pi$ , where the value is greater than  $\pi$  to ensure the value in the range. Similarly, we add  $2\pi$ , where the value is smaller than  $-\pi$ . When the response falls in the defined range, Figure 4 shows the displacement contour for the screw dislocation. To the authors' best knowledge, the degenerate kernel for the angle-based fundamental solution was not found in the literature.

### 3. 2D Exterior Problem

For the problem of an infinite plane problem with a circular boundary under the screw dislocation as shown in Figure 5(a), the function of displacement field satisfies

$$\begin{aligned} \nabla^2 U_G(x) &= 0, \quad x \in \Omega, \\ U_G(\rho, \phi) \big|_{\phi=2\pi} - U_G(\rho, \phi) \big|_{\phi=0} &= b, \quad \rho > R, \end{aligned} \quad (3.1)$$

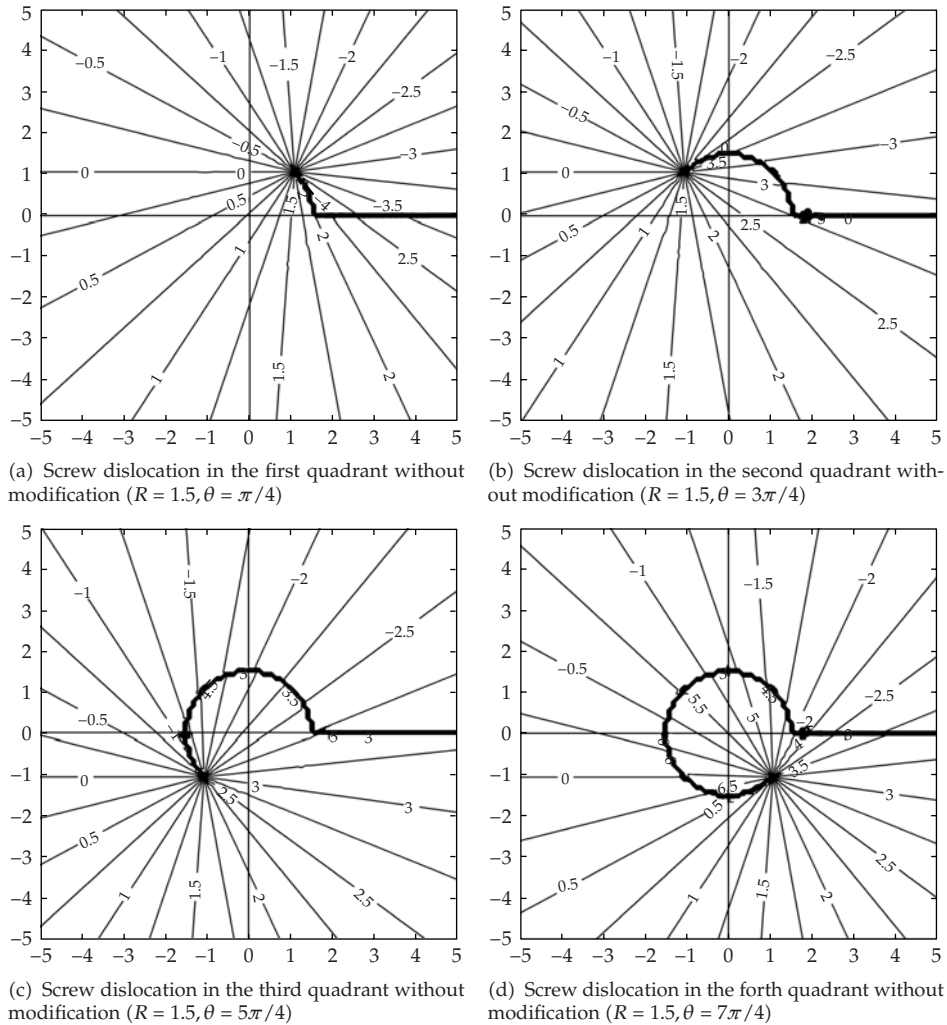

where  $\Omega$  is the domain of interest and  $b$  is the Burger's vector which is equal to  $2\pi$  in this paper. The boundary condition on the circular boundary is the Dirichlet type

$$U_G(x) \big|_{x \in B} = U_G(\rho, \phi) \big|_{\rho=a} = 0, \quad (3.2)$$

where  $a$  is the radius of the circular boundary and  $B$  is the boundary. By employing the image method, the image point is located outside the domain and the solution can be represented as follows:

$$U_G(x; s, s') = \psi(s, x) + \psi(s', x) + c, \quad (3.3)$$

where  $s'$  is the location of image point,  $c$  is a free constant, and

**Figure 3:** Screw dislocation in (a) the first, (b) the second, (c) the third, and (d) the fourth quadrant without modification.

$$\psi(s, x) = \theta + \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{\rho}{R}\right)^m \sin m(\theta - \phi), \quad \rho < R, \tag{3.4}$$

$$\psi(s', x) = \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R'}{\rho}\right)^m \sin m(\theta' - \phi), \quad \rho > R'.$$

In order to match the boundary condition and the Burger's vector, first the sum of series is independent of  $\phi$ . Therefore, we choose the collinear points  $s$  and  $s'$ , that is,  $\theta = \theta'$  and we have

$$\sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{a}{R}\right)^m \sin m(\theta - \phi) - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R'}{a}\right)^m \sin m(\theta - \phi) = 0. \tag{3.5}$$

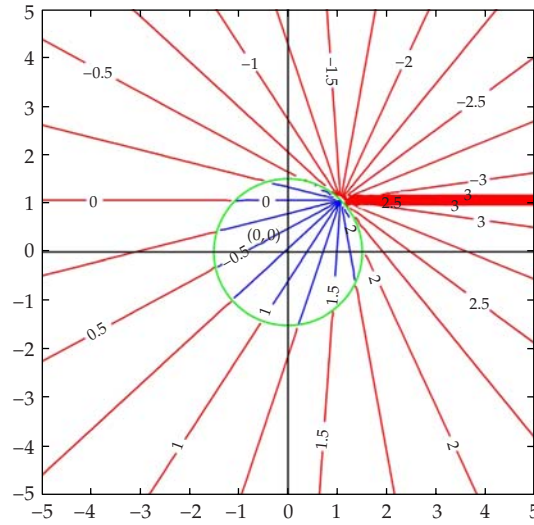

Figure 4: Screw dislocation in the first quadrant after modification ( $R = 1.5, \theta = \pi/4$ ).

Figure 5: 2D exterior problem (a) Dirichlet boundary condition and (b) Neumann boundary condition.

Finally, we can obtain the location of image point

$$\frac{R'}{a} = \frac{a}{R} \implies R' = \frac{a^2}{R} = \frac{a^2}{R}, \tag{3.6}$$

$$\psi(s, x) + \varphi(s', x) = \theta + \phi - \pi.$$

Second, we found that  $c$  is equal to  $(-\theta - \phi + \pi)$  and the solution  $U_G(x; s, s')$  automatically matches the boundary condition and Burger's vector. The displacement field of the closed-form Green's function can be obtained as below

$$U_G(x; s, s') = \psi(s, x) + \psi(s', x) - \theta - \phi + \pi. \quad (3.7)$$

For the domain ( $a < \rho < R$ ) as shown in Figure 6(a), the Green's function is expanded into

$$\begin{aligned} U_G(x; s, s') &= \psi(s, x) + \psi(s', x) - \theta - \phi + \pi \\ &= \theta + \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{\rho}{R}\right)^m \sin m(\theta - \phi) \\ &\quad + \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{a^2}{\rho R}\right)^m \sin m(\theta - \phi) - \theta - \phi + \pi \\ &= \sum_{m=1}^{\infty} \frac{1}{m} \left[ \left(\frac{\rho}{R}\right)^m - \left(\frac{a^2}{\rho R}\right)^m \right] \sin m(\theta - \phi), \quad a < \rho < R. \end{aligned} \quad (3.8)$$

Similarly, the Green's function in the other region ( $R < \rho < \infty$ ) is shown in Figure 6(b) and is expanded into

$$\begin{aligned} U_G(x; s, s') &= \psi(s, x) + \psi(s', x) - \theta - \phi + \pi \\ &= \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{R}{\rho}\right)^m \sin m(\theta - \phi) \\ &\quad + \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{a^2}{\rho R}\right)^m \sin m(\theta - \phi) - \theta - \phi + \pi \\ &= \phi - \theta - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left[ \left(\frac{R}{\rho}\right)^m + \left(\frac{a^2}{\rho R}\right)^m \right] \sin m(\theta - \phi), \quad R < \rho < \infty. \end{aligned} \quad (3.9)$$

For comparison, the closed-form solution of Smith's solution is expressed in terms of functions of complex variable

$$\begin{aligned} F(z) &= \frac{\mu_E b}{2\pi i} \log(z - z_0) + \frac{\mu_E b}{2\pi i} \log\left(\frac{a^2}{z} - \bar{z}_0\right), \\ U_G(x) &= \frac{1}{\mu_E} \operatorname{Re}[F(z)], \end{aligned} \quad (3.10)$$

where  $F(z)$  and  $\mu_E$  denote the complex function and shear modulus, respectively,  $\bar{z}_0$  denotes the conjugate of the position vector of the screw dislocation, and  $\operatorname{Re}[\cdot]$  denotes the real part. Figures 7(a) and 7(b) show the contour of displacement field by using the Smith's method [1] and the present approach, respectively. Good agreement is made.

**Figure 6:** Green's function of (a) the inner domain ( $a < \rho < R$ ) and (b) the outer domain ( $R < \rho < \infty$ ) for the exterior problem.

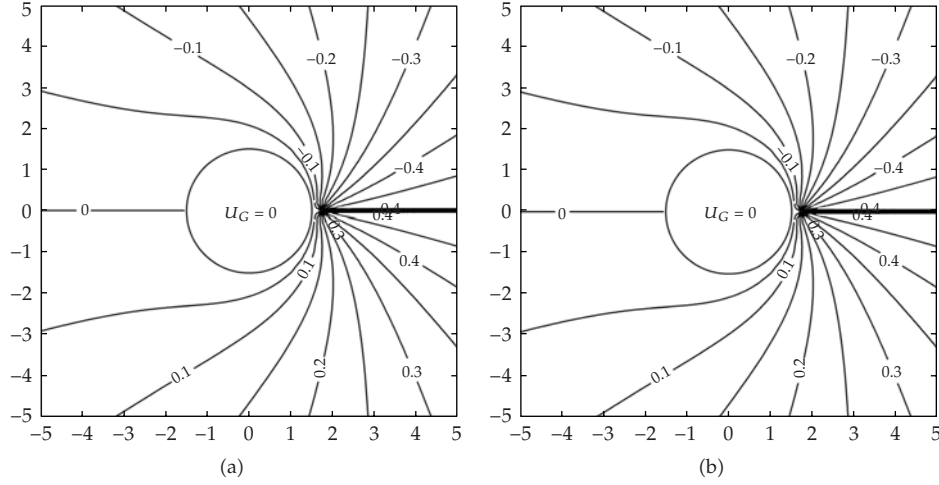

According to the successful experience of the Dirichlet boundary condition for the exterior problem, we extend our approach to the Neumann boundary condition, as shown in Figure 5(b),

$$\left. \frac{\partial U_G(x)}{\partial n_x} \right|_{x \in B} = \left. \frac{\partial U_G(\rho, \phi)}{\partial \rho} \right|_{\rho=a} = 0. \quad (3.11)$$

In a similar way, we have the closed-form Green's function for the Neumann boundary condition as

$$U_G(x; s, s') = \psi(s, x) - \psi(s', x) + \phi - \pi, \quad (3.12)$$

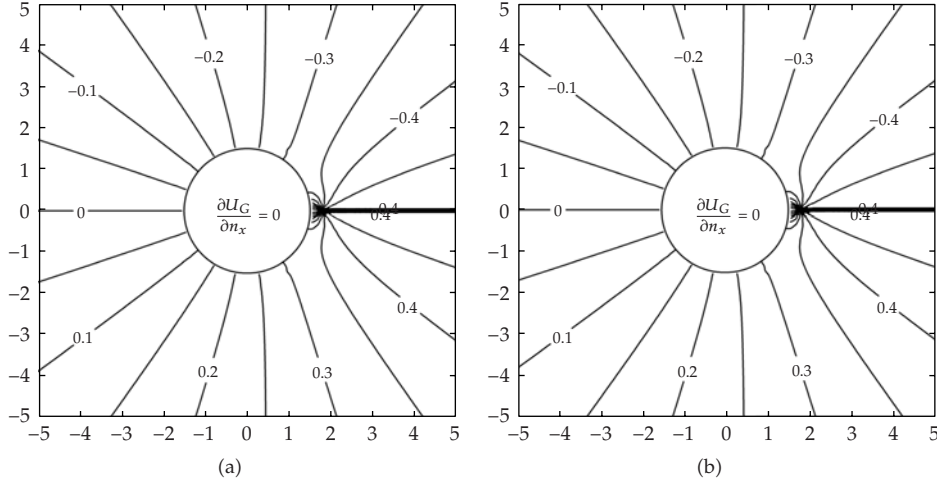

**Figure 7:** Displacement contour (Dirichlet boundary condition) by using (a) the Smith's method [1] and (b) the present method ( $M = 50$ ).

and the series form is expressed into two parts. For the domain ( $a < \rho < R$ ) as shown in Figure 6(a), the Green's function is expanded into

$$\begin{aligned}
 U_G(x; s, s') &= \psi(s, x) - \psi(s', x) + \phi - \pi \\
 &= \theta + \sum_{m=1}^{\infty} \frac{1}{m} \left( \frac{\rho}{R} \right)^m \sin m(\theta - \phi) \\
 &\quad - \phi + \pi + \sum_{m=1}^{\infty} \frac{1}{m} \left( \frac{a^2}{\rho R} \right)^m \sin m(\theta - \phi) + \phi - \pi \\
 &= \theta + \sum_{m=1}^{\infty} \frac{1}{m} \left[ \left( \frac{\rho}{R} \right)^m + \left( \frac{a^2}{\rho R} \right)^m \right] \sin m(\theta - \phi), \quad a < \rho < R.
 \end{aligned} \tag{3.13}$$

For the other domain as shown in Figure 6(b), we have

$$\begin{aligned}
 U_G(x; s, s') &= \psi(s, x) - \psi(s', x) + \phi - \pi \\
 &= \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left( \frac{R}{\rho} \right)^m \sin m(\theta - \phi) \\
 &\quad - \phi + \pi + \sum_{m=1}^{\infty} \frac{1}{m} \left( \frac{a^2}{\rho R} \right)^m \sin m(\theta - \phi) + \phi - \pi \\
 &= \phi - \pi - \sum_{m=1}^{\infty} \frac{1}{m} \left[ \left( \frac{R}{\rho} \right)^m - \left( \frac{a^2}{\rho R} \right)^m \right] \sin m(\theta - \phi), \quad R < \rho < \infty.
 \end{aligned} \tag{3.14}$$

**Figure 8:** Displacement contour (Neumann boundary condition) by using (a) the Smith's method [1] and (b) the present method ( $M = 50$ ).

For comparison, the closed-form solution of Smith's solution is expressed in terms of functions of complex variable

$$F(z) = \frac{\mu_E b}{2\pi i} \log(z - z_0) - \frac{\mu_E b}{2\pi i} \log\left(\frac{a^2}{z} - \bar{z}_0\right), \quad (3.15)$$

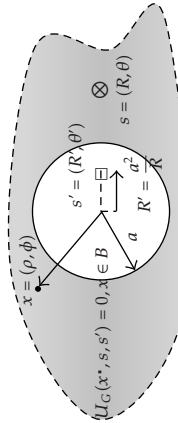

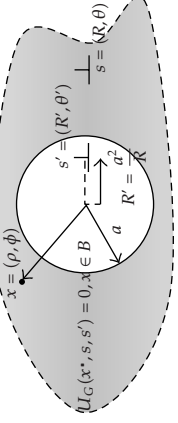

$$U_G(x) = \frac{1}{\mu_E} \operatorname{Re}[F(z)].$$

Figures 8(a) and 8(b) show the contour of displacement field by using the Smith's method [1] and the present method, respectively. It is found that the result of the present approach is acceptable. Based on the image method, it is a straightforward, logical, and natural way to find that the location of image point is  $(a^2/R)$ . We summarize the result of our approach for the screw dislocation and compare with those of Chen and Wu for the source case in Tables 1 and 2.

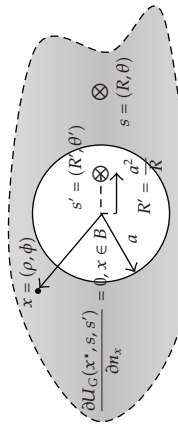

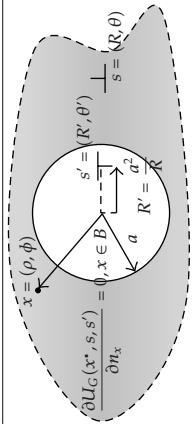

#### 4. Conclusions

For the screw dislocation problem with circular boundaries, we have proposed a natural approach to construct the screw dislocation solution by using the degenerate kernel. The angle-based fundamental solution for screw dislocation was derived in terms of degenerate kernel in this paper. Based on this expression, the image location can be determined instead of using reciprocal radius. Two examples, including an infinite plane with a circular hole subject to the Dirichlet and Neumann boundary conditions, were used demonstrate the validity of the present formulation.

**Table 1:** Comparison for the source or sink and the screw dislocation (Dirichlet B. C.).
